HIGHLIGHTS OF PRESCRIBING INFORMATION
These highlights do not include all the information needed to use TOUJEO safely and effectively. See full prescribing information for TOUJEO.

TOUJEO (insulin glargine injection) U-300, for subcutaneous use
Initial U.S. Approval: 2015

---RECENT MAJOR CHANGES---
Dosage and Administration (2.1, 2.4) 3/2018

---INDICATIONS AND USAGE---
TOUJEO is a long-acting human insulin analog indicated to improve glycemic control in adults with diabetes mellitus. (1)

Limitations of Use:
Not recommended for treating diabetic ketoacidosis. (1)

---DOSE AND ADMINISTRATION---
• Individualize dose based on type of diabetes, metabolic needs, blood glucose monitoring results and glycemic control goal. (2.1, 2.2, 2.3)
• Administer subcutaneously once daily at any time during the day, at the same time every day. (2.1)
• Rotate injection sites to reduce the risk of lipodystrophy. (2.1)
• Do not dilute or mix with any other insulin or solution. (2.1)
• Closely monitor glucose when changing to TOUJEO and during initial weeks thereafter. (2.3)

---DOSE FORMS AND STRENGTHS---
Injection: 300 units/mL insulin glargine in:
• 1.5 mL TOUJEO SoloStar disposable prefilled pen (3)
• 3 mL TOUJEO Max SoloStar disposable prefilled pen (3)

---CONTRAINDICATIONS---
• During episodes of hypoglycemia (4)
• Hypersensitivity to TOUJEO or one of its excipients (4)

---WARNINGS AND PRECAUTIONS---
• Never share a TOUJEO SoloStar or TOUJEO Max SoloStar- disposable prefilled pen between patients, even if the needle is changed (5.1)
• Hypoglycemia or hypoglycemia with changes in insulin regimen: Carry out under close medical supervision. (5.2)

---ADVERSE REACTIONS---
Adverse reactions commonly associated with TOUJEO (≥5%) are:
• Hypoglycemia, allergic reactions, injection site reaction, lipodystrophy, pruritus, rash, edema and weight gain. (6.1, 6.2)
To report SUSPECTED ADVERSE REACTIONS, contact sanofi- aventis at 1-800-633-1610 or FDA at 1-800-FDA-1088 or www.fda.gov/medwatch.

---DRUG INTERACTIONS---
• Drugs that affect glucose metabolism: Adjustment of insulin dosage may be needed; closely monitor blood glucose. (7)
• Antidiuretic Drugs (e.g., beta-blockers, clonidine, guanethidine, and reserpine): Signs and symptoms of hypoglycemia may be reduced or absent. (7)

---USE IN SPECIFIC POPULATIONS---
• Pregnancy: Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. (8.1)

See 17 for PATIENT COUNSELING INFORMATION and FDA-approved patient labeling.

Revised: 3/2018

*Sections or subsections omitted from the full prescribing information are not listed.
FULL PRESCRIBING INFORMATION

1 INDICATIONS AND USAGE
TOUJEO is indicated to improve glycemic control in adults with diabetes mellitus.

Limitations of Use:
TOUJEO is not recommended for the treatment of diabetic ketoacidosis.

2 DOSAGE AND ADMINISTRATION

2.1 General Dosing Instructions
- TOUJEO is available in 2 disposable prefilled pens:
  - TOUJEO SoloStar contains 450 units of TOUJEO U-300. It delivers doses in 1 unit increments and can deliver up to 80 units in a single injection.
  - TOUJEO Max SoloStar contains 900 units of TOUJEO U-300. It delivers doses in 2 unit increments and can deliver up to 160 units in a single injection. It is recommended for patients requiring at least 20 units per day.
- Inject TOUJEO subcutaneously once a day into the abdominal area, thigh, or deltoid at the same time each day.
- Rotate injection sites within the same region from one injection to the next to reduce the risk of lipodystrophy [see Adverse Reactions (6.1)].
- Individualize and titrate the dosage of TOUJEO based on the individual’s metabolic needs, blood glucose monitoring results, and glycemic control goal.
- To minimize the risk of hypoglycemia, titrate the dose of TOUJEO no more frequently than every 3 to 4 days.
- Dosage adjustments may be needed with changes in physical activity, changes in meal patterns (i.e., macronutrient content or timing of food intake), changes in renal or hepatic function or during acute illness to minimize the risk of hypoglycemia or hyperglycemia [see Warnings and Precautions (5.2) and Use in Specific Populations (8.6, 8.7)].
- Use TOUJEO with caution in patients with visual impairment who may rely on audible clicks to dial their dose.

2.2 Starting Dose in Insulin-Naive Patients
Type 1 Diabetes
- The recommended starting dose of TOUJEO in insulin-naive patients with type 1 diabetes is approximately one-third to one-half of the total daily insulin dose. The remainder of the total daily insulin dose should be given as a short-acting insulin and divided between each daily meal. As a general rule, 0.2 to 0.4 units of insulin per kilogram of body weight can be used to calculate the initial total daily insulin dose in insulin-naive patients with type 1 diabetes.
- The maximum glucose lowering effect of a dose of TOUJEO may take five days to fully manifest and the first TOUJEO dose may be insufficient to cover metabolic needs in the first 24 hours of use [see Clinical Pharmacology (12.2)]. To minimize risks associated with
insufficient insulinization when initiating TOUJEO, monitor glucose daily, titrate TOUJEO per instructions, and adjust coadministered glucose-lowering therapies per standard of care.

**Type 2 Diabetes**

- The recommended starting dose of TOUJEO in insulin-naive patients with type 2 diabetes is 0.2 units per kilogram of body weight once daily. The dosage of other antidiabetic drugs may need to be adjusted when starting TOUJEO to minimize the risk of hypoglycemia [see Warnings and Precautions (5.3)].

**2.3 Starting Dose in Patients with Either Type 1 or Type 2 Diabetes Already on Insulin Therapy**

- To minimize the risk of hypoglycemia when changing patients from a once-daily long-acting or intermediate-acting insulin product to TOUJEO, the starting dose of TOUJEO can be the same as the once-daily long-acting dose. For patients controlled on LANTUS (insulin glargine, 100 units/mL) expect that a higher daily dose of TOUJEO will be needed to maintain the same level of glycemic control [see Clinical Pharmacology (12.2) and Clinical Studies (14.1)].

- To minimize the risk of hypoglycemia when changing patients from twice-daily NPH insulin to once-daily TOUJEO, the recommended starting TOUJEO dose is 80% of the total daily NPH dosage.

- To minimize the risk of hyperglycemia when changing patients to TOUJEO, monitor glucose frequently in the first weeks of therapy titrate the dose of TOUJEO per instructions and the dose of other glucose-lowering therapies per standard of care [see Warning and Precautions (5.2) and Clinical Pharmacology (12.2)].

**2.4 Important Administration Instructions**

- Always check insulin labels before administration [see Warnings and Precautions (5.4)].

- When changing between TOUJEO SoloStar and TOUJEO Max SoloStar, if the patient’s previous dose was an odd number, the dose should be increased or decreased by 1 unit.

- The dose counter of the TOUJEO SoloStar or TOUJEO Max SoloStar disposable prefilled pen shows the number of units of TOUJEO to be injected and no conversion is required.

- Instruct patients to visually inspect the TOUJEO solution for particulate matter and discoloration prior to administration and only use if the solution is clear and colorless with no visible particles.

- Do not administer TOUJEO intravenously, intramuscularly, or in an insulin pump.

- Do not dilute or mix TOUJEO with any other insulin products or solutions.

- Never transfer TOUJEO from the cartridges of the TOUJEO SoloStar or TOUJEO Max SoloStar prefilled pen into a syringe for administration [see Warnings and Precautions (5.4)].

**3 DOSAGE FORMS AND STRENGTHS**

Injection: 300 units per mL of insulin glargine available as a clear, colorless, solution in:
• 1.5 mL TOUJEO SoloStar disposable prefilled pen (450 units/1.5 mL).
• 3 mL TOUJEO Max SoloStar disposable prefilled pen (900 units/3 mL).

4 CONTRAINDICATIONS
TOUJEO is contraindicated:
• During episodes of hypoglycemia [see Warnings and Precautions (5.3)].
• In patients with hypersensitivity to insulin glargine or one of its excipients [see Warnings and Precautions (5.5)].

5 WARNINGS AND PRECAUTIONS
5.1 Never Share a TOUJEO SoloStar or TOUJEO Max SoloStar Pen Between Patients
TOUJEO SoloStar or TOUJEO Max SoloStar disposable prefilled pens must never be shared between patients, even if the needle is changed. Pen sharing poses a risk for transmission of blood-borne pathogens.

5.2 Hyperglycemia or Hypoglycemia with Changes in Insulin Regimen
Changes in insulin strength, manufacturer, type, or method of administration may affect glycemic control and predispose to hypoglycemia [see Warnings and Precautions (5.3)] or hyperglycemia. These changes should be made cautiously and only under close medical supervision, and the frequency of blood glucose monitoring should be increased. For patients with type 2 diabetes, dosage adjustments of concomitant oral antidiabetic products may be needed.

On a unit-to-unit basis, TOUJEO has a lower glucose lowering effect than LANTUS [see Clinical Pharmacology (12.2)]. In clinical trials, patients who changed to TOUJEO from other basal insulins experienced higher average fasting plasma glucose levels in the first weeks of therapy compared to patients who were changed to LANTUS. To minimize the risk of hyperglycemia when initiating TOUJEO monitor glucose daily, titrate TOUJEO according to labeling instructions, and adjust coadministered glucose-lowering therapies per standard of care [see Dosage and Administration (2.2, 2.3)]. Higher doses of TOUJEO were required to achieve similar levels of glucose control compared to LANTUS in clinical trials [see Clinical Studies (14.1)].

The onset of action of TOUJEO develops over 6 hours following an injection. In type 1 diabetes patients treated with IV insulin, consider the longer onset of action of TOUJEO before stopping IV insulin. The full glucose lowering effect may not be apparent for at least 5 days [see Dosage and Administration (2.2) and Clinical Pharmacology (12.2)].

5.3 Hypoglycemia
Hypoglycemia is the most common adverse reaction associated with insulin, including TOUJEO. Severe hypoglycemia can cause seizures, may be life-threatening, or cause death. Hypoglycemia
can impair concentration ability and reaction time; this may place an individual and others at risk in situations where these abilities are important (e.g., driving, or operating other machinery). Hypoglycemia can happen suddenly and symptoms may differ in each individual and change over time in the same individual. Symptomatic awareness of hypoglycemia may be less pronounced in patients with longstanding diabetes, in patients with diabetic nerve disease, in patients using medications that block the sympathetic nervous system (e.g., beta-blockers) [see Drug Interactions (7)], or in patients who experience recurrent hypoglycemia.

Risk Factors for Hypoglycemia

The timing of hypoglycemia usually reflects the time-action profile of the administered insulin formulation. As with all insulin preparations, the glucose lowering effect time course of TOUJEO may vary in different individuals or at different times in the same individual and depends on many conditions, including the area of injection as well as the injection site blood supply and temperature [see Clinical Pharmacology (12.2)]. Other factors which may increase the risk of hypoglycemia include changes in meal pattern (e.g., macronutrient content or timing of meals), changes in level of physical activity, or changes to coadministered medication [see Drug Interactions (7)]. Patients with renal or hepatic impairment may be at higher risk of hypoglycemia [see Use in Specific Populations (8.6, 8.7)].

Risk Mitigation Strategies for Hypoglycemia

Patients and caregivers must be educated to recognize and manage hypoglycemia. Self-monitoring of blood glucose plays an essential role in the prevention and management of hypoglycemia. In patients at higher risk for hypoglycemia and patients who have reduced symptomatic awareness of hypoglycemia, increased frequency of blood glucose monitoring is recommended. To minimize the risk of hypoglycemia do not administer TOUJEO intravenously, intramuscularly, or in an insulin pump, or dilute or mix TOUJEO with any other insulin products or solutions.

5.4 Medication Errors

Accidental mix-ups between basal insulin products and other insulins, particularly rapid-acting insulins, have been reported. To avoid medication errors between TOUJEO and other insulins, instruct patients to always check the insulin label before each injection.

To avoid dosing errors and potential overdose, never use a syringe to remove TOUJEO from the TOUJEO SoloStar or TOUJEO Max SoloStar prefilled pen into a syringe [see Dosage and Administration (2.4) and Warnings and Precautions (5.3)].

5.5 Hypersensitivity and Allergic Reactions

Severe, life-threatening, generalized allergy, including anaphylaxis, can occur with insulin products, including TOUJEO. If hypersensitivity reactions occur, discontinue TOUJEO; treat per standard of care and monitor until symptoms and signs resolve [see Adverse Reactions (6)]. TOUJEO is contraindicated in patients who have had hypersensitivity reactions to insulin glargine or other of the excipients [see Contraindications (4)].
5.6 **Hypokalemia**

All insulin products, including TOUJEO, cause a shift in potassium from the extracellular to intracellular space, possibly leading to hypokalemia. Untreated hypokalemia may cause respiratory paralysis, ventricular arrhythmia, and death. Monitor potassium levels in patients at risk for hypokalemia, if indicated (e.g., patients using potassium-lowering medications, patients taking medications sensitive to serum potassium concentrations).

5.7 **Fluid Retention and Heart Failure with Concomitant Use of PPAR-gamma Agonists**

Thiazolidinediones (TZDs), which are peroxisome proliferator-activated receptor (PPAR)-gamma agonists, can cause dose-related fluid retention, particularly when used in combination with insulin. Fluid retention may lead to or exacerbate heart failure. Patients treated with insulin, including TOUJEO, and a PPAR-gamma agonist should be observed for signs and symptoms of heart failure. If heart failure develops, it should be managed according to current standards of care, and discontinuation or dose reduction of the PPAR-gamma agonist must be considered.

6 **ADVERSE REACTIONS**

The following adverse reactions are discussed elsewhere:

- Hypoglycemia [see Warnings and Precautions (5.3)]
- Medication Errors [see Warnings and Precautions (5.4)]
- Hypersensitivity and allergic reactions [see Warnings and Precautions (5.5)]
- Hypokalemia [see Warnings and Precautions (5.6)]

6.1 **Clinical Trials Experience**

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug, and may not reflect the rates actually observed in clinical practice.

The data in Table 1 reflect the exposure of 304 patients with type 1 diabetes to TOUJEO with mean exposure duration of 23 weeks. The type 1 diabetes population had the following characteristics: Mean age was 46 years and mean duration of diabetes was 21 years. Fifty-five percent were male, 86% were Caucasian, 5% were Black or African American, and 5% were Hispanic. At baseline, the mean eGFR was 82 mL/min/1.73 m² and 35% of patients had eGFR ≥90 mL/min/1.73 m². The mean BMI was 28 kg/m². HbA1c at baseline was greater or equal to 8% in 58% of patients.

The data in Table 2 reflect the exposure of 1242 patients with type 2 diabetes to TOUJEO with mean exposure duration of 25 weeks. The type 2 diabetes population had the following characteristics: Mean age was 59 years and mean duration of diabetes was 13 years. Fifty-three percent were male, 88% were Caucasian, 7% were Black or African American, and 17% were Hispanic. At baseline, mean eGFR was 79 mL/min/1.73 m² and 27% of patients had an eGFR ≥90 mL/min/1.73 m². The mean BMI was 35 kg/m². HbA1c at baseline was greater or equal to 8% in 66% of patients.
Common adverse reactions were defined as reactions occurring in ≥5% of the population studied. Common adverse reactions occurring for TOUJEO-treated subjects during clinical trials in patients with type 1 diabetes mellitus and type 2 diabetes mellitus are listed in Table 1 and Table 2, respectively. Hypoglycemia is discussed in a dedicated subsection below.

* one of the trials in type 2 diabetes included mealtime insulin.

Hypoglycemia

Hypoglycemia is the most commonly observed adverse reaction in patients using insulin, including TOUJEO [see Warnings and Precautions (5.3)]. In the TOUJEO program, severe hypoglycemia was defined as an event requiring assistance of another person to administer a resuscitative action and documented symptomatic hypoglycemia was defined as an event with typical symptoms of hypoglycemia accompanied by a self-monitored or plasma glucose value equal to or less than 54 mg/dL.

The incidence of severe hypoglycemia in patients with type 1 diabetes receiving TOUJEO as part of a multiple daily injection regimen was 6.6% at 26 weeks. The incidence of documented symptomatic hypoglycemia was 69% at 26 weeks. There were no clinically important differences in hypoglycemia between TOUJEO and LANTUS among type 1 diabetes patients.

The incidence of severe hypoglycemia in patients with type 2 diabetes was 5% at 26 weeks in patients receiving TOUJEO as part of a multiple daily injection regimen, and 1.0% and 0.9% respectively at 26 weeks in the two studies where patients received TOUJEO as part of a basal-insulin only regimen. The incidence of documented symptomatic hypoglycemia in patients with type 2 diabetes receiving TOUJEO ranged from 8% to 37% at 26 weeks and the highest risk was again seen in patients receiving TOUJEO as part of a multiple daily injection regimen.
Insulin Initiation and Intensification of Glucose Control

Intensification or rapid improvement in glucose control has been associated with a transitory, reversible ophthalmologic refraction disorder, worsening of diabetic retinopathy, and acute painful peripheral neuropathy. However, long-term glycemic control decreases the risk of diabetic retinopathy and neuropathy.

Peripheral Edema

Insulin, including TOUJEO, may cause sodium retention and edema, particularly if previously poor metabolic control is improved by intensified insulin therapy.

Lipodystrophy

Long-term use of insulin, including TOUJEO, can cause lipoatrophy (depression in the skin) or lipohypertrophy (enlargement or thickening of tissue) in some patients and may affect insulin absorption [see Dosage and Administration (2.1)].

Weight Gain

Weight gain has occurred with some insulin therapies including TOUJEO and has been attributed to the anabolic effects of insulin and the decrease in glucosuria.

Allergic Reactions

Some patients taking insulin therapy, including TOUJEO have experienced erythema, local edema, and pruritus at the site of injection. These conditions were usually self-limiting. Severe cases of generalized allergy (anaphylaxis) have been reported [see Warnings and Precautions (5.5)].

Cardiovascular Safety

No clinical studies to establish the cardiovascular safety of TOUJEO have been conducted. A cardiovascular outcomes trial, ORIGIN, has been conducted with LANTUS. It is unknown whether the results of ORIGIN can be applied to TOUJEO.

The Outcome Reduction with Initial Glargine Intervention trial (i.e., ORIGIN) was an open-label, randomized, 12,537 patient study that compared LANTUS to standard care on the time to first occurrence of a major adverse cardiovascular event (MACE). MACE was defined as the composite of CV death, nonfatal myocardial infarction and nonfatal stroke. The incidence of MACE was similar between LANTUS and standard care in ORIGIN (Hazard Ratio [95% CI] for MACE; 1.02 [0.94, 1.11]).

In the ORIGIN trial, the overall incidence of cancer (all types combined) (Hazard Ratio [95% CI]; 0.99 [0.88, 1.11]) or death from cancer (Hazard Ratio [95% CI]; 0.94 [0.77, 1.15]) was also similar between treatment groups.

6.2 Immunogenicity

As with all therapeutic proteins, there is potential for immunogenicity.

In a 6-month study of type 1 diabetes patients, 79% of patients who received TOUJEO once daily were positive for anti-insulin antibodies (AIA) at least once during the study, including 62% that were positive at baseline and 44% of patients who developed antidrug antibody (i.e., anti-insulin glargine antibody [ADA]) during the study. Eighty percent of the AIA-positive
patients on TOUJEO with antibody test at baseline remained AIA positive at month 6.

In two 6-month studies in type 2 diabetes patients, 25% of patients who received TOUJEO once daily were positive for AIA at least once during the study, including 42% who were positive at baseline and 20% of patients who developed ADA during the study. Ninety percent of the AIA-positive patients on TOUJEO with antibody test at baseline, remained AIA positive at month 6.

The detection of antibody formation is highly dependent on the sensitivity and specificity of the assay and may be influenced by several factors such as: assay methodology, sample handling, timing of sample collection, concomitant medication, and underlying disease. For these reasons, comparison of the incidence of antibodies to TOUJEO with the incidence of antibodies in other studies or to other products may be misleading.

7 DRUG INTERACTIONS

Table 3 includes clinically significant drug interactions with TOUJEO

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Risk Summary

All pregnancies have a background risk of birth defects, loss, or other adverse outcome regardless of drug exposure. This background risk is increased in pregnancies complicated by
hyperglycemia and may be decreased with good metabolic control. It is essential for patients
with diabetes or a history of gestational diabetes to maintain good metabolic control before
conception and throughout pregnancy. In patients with diabetes or gestational diabetes, insulin
requirements may decrease during the first trimester, generally increase during the second and
third trimesters, and rapidly decline after delivery. Careful monitoring of glucose control is
essential in these patients. Therefore, female patients should be advised to tell their physicians if
they intend to become, or if they become, pregnant while taking TOUJEIO.

Human data
There are no clinical studies of the use of TOUJEIO in pregnant women. Because animal
reproduction studies are not always predictive of human response, this drug should be used
during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Animal data
Subcutaneous reproduction and teratology studies have been performed with insulin glargine and
regular human insulin in rats and Himalayan rabbits. Insulin glargine was given to female rats
before mating, during mating, and throughout pregnancy at doses up to 0.36 mg/kg/day, which is
approximately 50 times the recommended human subcutaneous starting dose of 0.2 Units/kg/day
(0.007 mg/kg/day). In rabbits, doses of 0.072 mg/kg/day, which is approximately 10 times the
recommended human subcutaneous starting dose of 0.2 Units/kg/day (0.007 mg/kg/day), were
administered during organogenesis. The effects of insulin glargine did not generally differ from
those observed with regular human insulin in rats or rabbits. However, in rabbits, five fetuses
from two litters of the high-dose group exhibited dilation of the cerebral ventricles. Fertility and
early embryonic development appeared normal.

8.3 Nursing Mothers
Endogenous insulin is present in human milk; it is unknown whether insulin glargine is excreted
in human milk. Because many drugs, including human insulin, are excreted in human milk,
cautions should be exercised when TOUJEIO is administered to a nursing woman. Use of
TOUJEIO is compatible with breastfeeding, but women with diabetes who are lactating may
require adjustments of their insulin doses.

8.4 Pediatric Use
The safety and effectiveness of TOUJEIO have not been established in pediatric patients.

8.5 Geriatric Use
In controlled clinical studies, 30 of 304 (9.8%) TOUJEIO-treated patients with type 1 diabetes
and 327 of 1242 (26.3%) TOUJEIO-treated patients with type 2 diabetes were ≥65 years of age,
among them 2.0% of the patients with type 1 and 3.0% of the patients with type 2 diabetes were
≥75 years of age. No overall differences in effectiveness and safety were observed in the
subgroup analyses across the age groups.

Nevertheless, caution should be exercised when TOUJEIO is administered to geriatric patients. In
elderly patients with diabetes, the initial dosing, dose increments, and maintenance dosage
should be conservative to avoid hypoglycemia [see Warnings and Precautions (5.3), Adverse
Reactions (6), and Clinical Studies (14)].
8.6 Hepatic Impairment
The effect of hepatic impairment on the pharmacokinetics of TOUJELO has not been studied. Frequent glucose monitoring and dose adjustment may be necessary for TOUJELO in patients with hepatic impairment [see Warnings and Precautions (5.3)].

8.7 Renal Impairment
The effect of renal impairment on the pharmacokinetics of TOUJELO has not been studied. Some studies with human insulin have shown increased circulating levels of insulin in patients with renal failure. Recent glucose monitoring and dose adjustment may be necessary for TOUJELO in patients with renal impairment [see Warnings and Precautions (5.3)].

8.8 Obesity
No overall differences in effectiveness and safety were observed in subgroup analyses based on BMI.

10 OVERDOSAGE
Excess insulin administration may cause hypoglycemia and hypokalemia [see Warnings and Precautions (5.3, 5.6)]. Mild episodes of hypoglycemia can be treated with oral glucose. Adjustments in drug dosage, meal patterns, or physical activity level may be needed. More severe episodes of hypoglycemia with coma, seizure, or neurologic impairment may be treated with intramuscular/subcutaneous glucagon or concentrated intravenous glucose. Sustained carbohydrate intake and observation may be necessary because hypoglycemia may recur after apparent clinical recovery. Hypokalemia must be corrected appropriately.

11 DESCRIPTION
TOUJELO (insulin glargine injection) is a long-acting insulin supplied as a sterile solution for subcutaneous injection containing 300 units/mL of insulin glargine.

Insulin glargine is a human insulin analog produced by recombinant DNA technology utilizing a nonpathogenic laboratory strain of Escherichia coli (K12) as the production organism. Insulin glargine differs from human insulin in that the amino acid asparagine at position A21 is replaced by glycine and two arginines remain at the C-terminus of the B-chain. Chemically, insulin glargine is 21^[Gly]-31^B^-32^B^-Di-Arg -human insulin and has the empirical formula C267H404N72O78S6 and a molecular weight of 6063. Insulin glargine has the following structural formula:
Each milliliter of TOUJEO contains 300 units (10.91 mg) insulin glargine dissolved in a clear aqueous fluid.

The 1.5 mL TOUJEO SoloStar disposable prefilled pen presentation contains the following inactive ingredients per mL: 90 mcg zinc, 2.7 mg m-cresol, 20 mg glycerol 85%, and water for injection.

The 3 mL TOUJEO Max SoloStar disposable prefilled pen presentation contains the following inactive ingredients per mL: 90 mcg zinc, 2.7 mg m-cresol, 20 mg glycerol 85%, and water for injection.

The pH is adjusted by addition of aqueous solutions of hydrochloric acid and sodium hydroxide. TOUJEO has a pH of approximately 4. At pH 4, insulin glargine is completely soluble. After injection into the subcutaneous tissue, the acidic solution is neutralized, leading to formation of a precipitate from which small amounts of insulin glargine are slowly released.

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

The primary activity of insulin, including insulin glargine, is regulation of glucose metabolism. Insulin and its analogs lower blood glucose by stimulating peripheral glucose uptake, especially by skeletal muscle and fat, and by inhibiting hepatic glucose production. Insulin inhibits lipolysis and proteolysis, and enhances protein synthesis.

12.2 Pharmacodynamics

Onset of Action

The pharmacodynamic profiles for TOUJEO given subcutaneously as a single dose of 0.4, 0.6, or 0.9 U/kg in a euglycemic clamp study in patients with type 1 diabetes showed that on average, the onset of action develops over 6 hours post dose for all three single doses of TOUJEO.

Single-Dose Pharmacodynamics

The pharmacodynamics for single 0.4, 0.6, and 0.9 U/kg doses of TOUJEO in 24 patients with type 1 diabetes mellitus was evaluated in a euglycemic clamp study. On a unit-to-unit basis, TOUJEO had a lower maximum (GIR\textsubscript{max}) and 24-hour glucose lowering effect (GIR-AUC\textsubscript{0-24}).
compared to LANTUS. The overall glucose lowering effect of TOUJEO 0.4 U/kg was 12% of the glucose lowering effect of an equivalent dose of LANTUS. Glucose lowering at least 30% of the effect of a single 0.4 U/kg dose of LANTUS was not observed until the single dose of TOUJEO exceeded 0.6 U/kg.

**Multiple Once-Daily Dose Pharmacodynamics**

The pharmacodynamics of TOUJEO after 8 days of daily injection was evaluated in 30 patients with type 1 diabetes. At steady state, the 24-hour glucose lowering effect (GIR-AUC$_{0-24}$) of TOUJEO 0.4 U/kg was approximately 27% lower with a different distribution profile than that of an equivalent dose of LANTUS [see Dosage and Administration (2), Warning and Precautions (5.2), and Clinical Pharmacology (12.3)]. The glucose lowering effect of a TOUJEO dose increased with each daily administration.

The pharmacodynamic profile for TOUJEO given subcutaneously as multiple once-daily subcutaneous injections of 0.4 U/kg in a euglycemic clamp study in patients with type 1 diabetes is shown in Figure 1.

**Figure 1: Glucose Infusion Rate in Patients with Type 1 Diabetes in Multiple-Dose Administration of TOUJEO**

![Graph showing glucose infusion rate](image)

Glucose infusion rate: determined as amount of glucose infused to maintain constant plasma glucose levels.

**12.3 Pharmacokinetics**

**Absorption and Bioavailability**

The pharmacokinetic profiles for single 0.4, 0.6, and 0.9 U/kg doses of TOUJEO in 24 patients with type 1 diabetes mellitus was evaluated in a euglycemic clamp study. The median time to maximum serum insulin concentration was 12 (8-14), 12 (12-18), and 16 (12-20) hours, respectively. Mean serum insulin concentrations declined to the lower limit of quantitation of 5.02 µU/mL by 16, 28, and beyond 36 hours, respectively.

Steady-state insulin concentrations are reached by at least 5 days of once-daily subcutaneous administration of 0.4 U/kg to 0.6 U/kg doses of TOUJEO over 8 days in patients with type 1 diabetes mellitus.

After subcutaneous injection of TOUJEO, the intra-subject variability, defined as the coefficient of variation for the insulin exposure during 24 hours was 21.0% at steady state.
Elimination

After subcutaneous injection of TOUJEO in diabetic patients, insulin glargine is metabolized at the carboxyl terminus of the B-chain with formation of two active metabolites M1 (21A-Gly-insulin) and M2 (21A-Gly-des-30B-Thr-insulin). The in vitro activity of M1 and M2 were similar to that of human insulin.

Specific Populations

Age (Geriatric Population and Pediatric Population), Race, and Sex: Effect of age, race, and sex on the pharmacokinetics of TOUJEO has not been evaluated.

Obesity: Effect of BMI on the pharmacokinetics of TOUJEO has not been evaluated.

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

In mice and rats, standard two-year carcinogenicity studies with insulin glargine were performed at doses up to 0.455 mg/kg, which was for the rat approximately 65 times the recommended human subcutaneous starting dose of 0.2 Units/kg/day (0.007 mg/kg/day). The findings in female mice were not conclusive due to excessive mortality in all dose groups during the study. Histiocytomas were found at injection sites in male rats (statistically significant) and male mice (not statistically significant) in acid vehicle containing groups. These tumors were not found in female animals, in saline control, or insulin comparator groups using a different vehicle. The relevance of these findings to humans is unknown.

Insulin glargine was not mutagenic in tests for detection of gene mutations in bacteria and mammalian cells (Ames and HGPRT test) and in tests for detection of chromosomal aberrations (cytogenetics in vitro in V79 cells and in vivo in Chinese hamsters).

In a combined fertility and prenatal and postnatal study in male and female rats at subcutaneous doses up to 0.36 mg/kg/day, which was approximately 50 times the recommended human subcutaneous starting dose of 0.2 Units/kg/day (0.007 mg/kg/day), maternal toxicity due to dose-dependent hypoglycemia, including some deaths, was observed. Consequently, a reduction of the rearing rate occurred in the high-dose group only. Similar effects were observed with NPH insulin.

14 CLINICAL STUDIES

14.1 Overview of Clinical Studies

The safety and effectiveness of TOUJEO given once daily was compared to that of once-daily LANTUS in open-label, randomized, active-control, parallel studies of up to 26 weeks in patients with type 1 diabetes mellitus and patients with type 2 diabetes mellitus (Tables 4 and 5). At trial end, the reduction in glycated hemoglobin (HbA1c) and fasting plasma glucose with TOUJEO titrated to goal was similar to that with LANTUS titrated to goal. At the end of the trial, depending on the patient population and concomitant therapy, patients were receiving a higher dose of TOUJEO than LANTUS.

14.2 Clinical Study in Adult Patients with Type 1 Diabetes

In an open-label, controlled study (Study A), patients with type 1 diabetes (n=546), were randomized to basal-bolus treatment with TOUJEO or LANTUS and treated for 26 weeks.
TOUJEO and LANTUS were administered once daily in the morning (time period covering from pre-breakfast until pre-lunch) or in the evening (time period defined as prior to the evening meal until at bedtime). A mealtime insulin analogue was administered before each meal. Mean age was 47.3 years and mean duration of diabetes was 21 years. Fifty-seven percent were male, 85.1% were Caucasian, 4.7% Black or African American, and 4.7% were Hispanic; 32.2% of patients had GFR >90 mL/min/1.73 m². The mean BMI was approximately 27.6 kg/m². At week 26, treatment with TOUJEO provided a mean reduction in HbA1c that met the prespecified noninferiority margin of 0.4% (Table 4). Patients treated with TOUJEO used 17.5% more basal insulin than patients treated with LANTUS. There were no clinically important differences in glycemic control when TOUJEO was administered once daily in the morning or in the evening. There were no clinically important differences in body weight between treatment groups.

Table 4: Type 1 Diabetes Mellitus – Adult (TOUJEO plus mealtime insulin versus LANTUS plus mealtime insulin)

* mITT: Modified intention-to-treat.
† Treatment difference: TOUJEO – LANTUS.
‡ “mealtime insulin” refers to insulin glulisine, insulin lispro or insulin aspart.

14.3 Clinical Studies in Adult Patients with Type 2 Diabetes

In a 26-week open-label, controlled study (study B, n=804), adults with type 2 diabetes were randomized to once-daily treatment in the evening with either TOUJEO or LANTUS. Short-acting mealtime insulin analogues with or without metformin were also administered. The average age was 60 years. The majority of patients were White (92.3%) and 52.9% were male; 20.3 % of patients had GFR >90 mL/min/1.73 m². The mean BMI was approximately 36.6 kg/m². At week 26, treatment with TOUJEO provided a mean reduction in HbA1c that met the prespecified noninferiority margin of 0.4% compared to LANTUS (Table 5). Patients treated with TOUJEO used 11% more basal insulin than patients treated with LANTUS. There were no clinically important differences in body weight between treatment groups.
In two open-label, controlled studies (n=1670), adults with type 2 diabetes mellitus were randomized to either TOUJEO or LANTUS once daily for 26 weeks as part of a regimen of combination therapy with noninsulin antidiabetic drugs. At the time of randomization, 808 patients were treated with basal insulin for more than 6 months (study C) and 862 patients were insulin-naive (study D).

In Study C, the average age was 58.2 years. The majority of patients were White (93.8%) and 45.9% were male; 32.8% of patients had GFR >90 mL/min/1.73 m². The mean BMI was approximately 34.8 kg/m². At week 26, treatment with TOUJEO provided a mean reduction in HbA1c that met the prespecified noninferiority margin of 0.4% compared to LANTUS (Table 5). Patients treated with TOUJEO used 12% more basal insulin than patients treated with LANTUS. There were no clinically important differences in body weight between treatment groups.

In Study D, the average age was 57.7 years. The majority of patients were White (78%) and 57.7% were male; 29% of patients had GFR >90 mL/min/1.73 m². The mean BMI was approximately 33 kg/m². At week 26, treatment with TOUJEO provided a mean reduction in HbA1c that met the prespecified noninferiority margin compared to LANTUS (Table 5). Patients treated with TOUJEO used 15% more basal insulin than patients treated with LANTUS. There were no clinically important differences in body weight between treatment groups.

16 HOW SUPPLIED/STORAGE AND HANDLING

16.1 How Supplied

TOUJEO is supplied as a clear and colorless solution containing 300 units per mL (U-300) of insulin glargine and is available in 2 disposable prefilled pen presentations:

<table>
<thead>
<tr>
<th>TOUJEO</th>
<th>Total volume</th>
<th>Concentration</th>

<td>900 units</td>
<td>160 units</td>
<td>2 units</td>
<td>0024-5871-02</td>
<td>2 pens/pack</td>
</tr>
</tbody>
</table>

Needles are not included in the packs of TOUJEO SoloStar or TOUJEO Max SoloStar disposable prefilled pen.

BD (such as BD Ultra-Fine®), Ypsomed (such as Clickfine®) or Owen Mumford (such as Unifine® Pentips®) needles‡ can be used in conjunction with TOUJEO SoloStar or TOUJEO Max SoloStar disposable prefilled pen and are sold separately.

A new sterile needle must be attached before each injection. TOUJEO SoloStar or TOUJEO Max SoloStar disposable prefilled pens must never be shared between patients, even if the needle is changed.

16.2 Storage

TOUJEO SoloStar or TOUJEO Max SoloStar disposable prefilled pen should not be stored in the freezer and should not be allowed to freeze. Discard TOUJEO disposable prefilled pen if it has been frozen.

Storage conditions are summarized in the following table:

<table>
<thead>
<tr>
<th></th>
<th>Not in-use (unopened) Refrigerated 36°F-46°F (2°C-8°C)</th>
<th>In-use (opened)* Room temperature only (Do not refrigerate) below 86°F (30°C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.5 mL TOUJEO SoloStar disposable prefilled pen</td>
<td>Until expiration date</td>
<td>42 days*</td>
</tr>
<tr>
<td>3 mL TOUJEO Max SoloStar disposable prefilled pen</td>
<td>Until expiration date</td>
<td>42 days*</td>
</tr>
</tbody>
</table>

* To prevent degradation, always store the prefilled pens with the cap on during in-use period.
17 PATIENT COUNSELING INFORMATION

Advise the patient to read the FDA-approved patient labeling (Patient Information and Instructions for Use).

Never Share a TOUJEO SoloStar or TOUJEO Max SoloStar Pen Between Patients

[See Warnings and Precautions (5.1).]

Advise patients that they must never share TOUJEO SoloStar or TOUJEO Max SoloStar pen with another person even if the needle is changed. Pen sharing poses a risk for transmission of blood-borne pathogens.

Hyperglycemia or Hypoglycemia

[See Warnings and Precautions (5.2, 5.3).]

Inform patients that hypoglycemia is the most common adverse reaction with insulin. Inform patients of the symptoms of hypoglycemia. Inform patients that the ability to concentrate and react may be impaired as a result of hypoglycemia. This may present a risk in situations where these abilities are especially important, such as driving or operating other machinery. Advise patients who have frequent hypoglycemia or reduced or absent warning signs of hypoglycemia to use caution when driving or operating machinery.

Advise patients that changes in insulin regimen can predispose to hyperglycemia or hypoglycemia. Advise patients that changes in insulin regimen should be made under close medical supervision.

Inform patients that if they change to TOUJEO from other basal insulins they may experience higher average fasting plasma glucose levels in the first weeks of therapy. Advise patients to monitor glucose daily when initiating TOUJEO.

Medication Errors

[See Warnings and Precautions (5.4).]

Instruct patients to always check the insulin label before each injection. The “300 units/mL (U-300)” is highlighted in honey gold on the labels of TOUJEO and TOUJEO Max SoloStar disposable prefilled pens.

Inform patients that TOUJEO (insulin glargine injection) 300 units/mL contains 3 times as much insulin in 1 mL as standard insulin (100 units/mL). To avoid dosing errors and potential overdose, instruct patients to never use a syringe to remove TOUJEO from the TOUJEO SoloStar or TOUJEO Max SoloStar disposable prefilled pen.

Inform patients that TOUJEO (insulin glargine injection) 300 units/mL is available in two disposable prefilled pens. The dose counter of TOUJEO SoloStar or TOUJEO Max SoloStar disposable prefilled pen shows the number of units of TOUJEO to be injected and no dose recalculation is required.

Instruct patients to follow the Instructions for Use and perform a safety test as described in Step 3 of the Instructions for Use. Failure to perform this step may result in not receiving the full dose. If this occurs, patients should increase the frequency of checking their blood glucose levels and might need to administer additional insulin.

TOUJEO SoloStar Prefilled Pen
TOUJEO SoloStar prefilled pen contains 450 units of TOUJEO. It delivers 1 to 80 units in a single injection. The dose can be adjusted by 1 unit at a time.

**TOUJEO Max SoloStar Prefilled Pen**

TOUJEO Max SoloStar prefilled pen contains 900 units of TOUJEO. It delivers 2 to 160 units in a single injection. The dose can be adjusted by 2 units at a time.

If safety tests are not performed before first use of a new pen, insulin underdose can occur. To reduce potential underdose, this pen is recommended for patients requiring at least 20 units per day.

Instruct patients to not re-use needles. A new needle must be attached before each injection. Re-use of needles increases the risk of blocked needles which may cause underdosing or overdosing. In the event of blocked needle, the patients must follow the instructions described in Step 3 of the Instructions for Use.

**Administration**

TOUJEO must only be used if the solution is clear and colorless with no particles visible. Patients must be advised that TOUJEO must NOT be diluted or mixed with any other insulin or solution.

**Pregnancy**

Advise patients to inform their health care professional if they are pregnant or are contemplating pregnancy.
